## Preface

This User's Guide describes the functions, commands, and parameters associated with HOST2TXT Transform.

---

## About this User's Guide

This User's Guide provides information about using HOST2TXT Transform, it helps you:

- Plan for transforming data from Adobe PDF (Portable Document Format) to AFP (Advanced Function Presentation) format.
- Install and configure HOST2TXT Transform.
- How to use HOST2TXT command.

The information in this user's guide is for users who install and use HOST2TXT Transform.

---

## Conventions Used in This User's Guide

This User's Guide uses consistent conventions for the following:

- Highlighting
- Syntax notation

### Highlighting

This User's Guide uses the following highlighting conventions:

- **Bold** Identifies commands, keywords, and other items, whose names or values are predefined by HOST2TXT Transform or must be entered as-is.
- *Italic* Identifies parameters whose actual names or values you supply.

### Syntax Notation

This User's Guide uses the following syntax notation:

- Italics within a command represent variables for which you must supply a value.  
For instance:

*-i inPath*

means that you need to replace the variable *inPath* with a value that represents any valid file system directory.

- Do not enter the following symbols as part of the command:

|              |     |
|--------------|-----|
| Vertical bar |     |
| Braces       | { } |
| Brackets     | [ ] |
| Underscore   | _   |
| Ellipsis     | ... |

The above symbols have the following meanings:

- A vertical bar, |, between values, indicates that you can only enter one of the values with the command.
- Braces, { }, around values indicate a required value, you must select one of the mutually exclusive values.
- Brackets, [ ], around parameters indicate that they are optional.
- An underscore, \_ indicates the default value, which HOST2TXT uses if you do not specify the parameter with a non-default value.
- An ellipsis, ..., following command or set of commands indicates the command or set of commands can be repeated.

---

## Chapter 1. Overview

HOST2TXT provides consistent, efficient, and high-performance transformation for the transactional high volume IBM mainframe line data to the text to be used for open system.

HOST2TXT can process the high volume line data from IBM systems, such as from IBM z/OS systems, Content Manager OnDemand, as well as via IBM FTP, NFS, PSF Download, etc.

---

### Functions at a Glance

HOST2TXT Transform provides the following advanced features, functions, and capabilities:

- Able to convert high-volume IBM mainframe line data in super-performance.
- Able to handle the line data carriage control in ANSI and Machine codes.
- Easy to specify the input data and output data encodings.
- High-performance conversion from IBM mainframe line data encoding in EBCDIC, SBCS-HOST/DBCS-HOST, to the text data encoding in ASCII, SBCS/DBCS for PC/Unix, and Unicode UTF-8.
- Able to process the different input data formats, such as IBM variable record length format, record delimited format, and fixed record length.
- Able to split output text data by the IBM generic index values.
- Able to split and output text files into the dynamic destination directories based on the IBM generic index values.

---

## Chapter 2. Installing HOST2TXT Transform for Windows

This chapter provides information on the server requirements and installation of the HOST2TXT Transform retail version for Windows.

---

### HOST2TXT for Windows Prerequisites

Here are the prerequisites to run HOST2TXT Transform for Windows:

1. Windows 7 or above, 64-bit.
2. Windows Server 2008 or above, 64-bit.

---

### Installing HOST2TXT on Windows

To install HOST2TXT Transform on a Windows server or workstation:

1. Log on to the Windows system as an administrator.
2. Run HOST2TXT Transform setup package you received.
3. Follow the instructions on the installation screens to install the package, the destination folder is `c:\HOST2TXT`.

---

### Applying License of HOST2TXT Transform Retail Version for Windows

#### Installing Soft-license Key

1. Open Windows Command Prompt, run command `HOST2TXT.exe`.
2. On HOST2TXT Transform Licensing GUI, copy the Serial Number, and then paste into an email to be sent to MakeAFP Support at [support@makeafp.com](mailto:support@makeafp.com) to request a software license key for your system.
3. Once a HOST2TXT Transform License key is received, you need to run HOST2TXT to apply the license key.

---

## Chapter 3. Installing HOST2TXT Transform for Linux

This chapter provides installation information of the HOST2TXT Transform retail version for Linux.

---

### Installing HOST2TXT on Linux

To install HOST2TXT Transform on a Linux server:

If install on the HOST2TXT default installation path `/usr/share/host2txt`, type the following command:

```
sudo sh host2txt_install.bin
```

If install on a user-defined specific path, type the following command:

```
sudo sh host2txt_install.bin your_host2txt_path_name
```

---

### Applying License of HOST2TXT Transform Retail Version for Linux

HOST2TXT Transform for Linux provides the soft-license key.

#### Installing Soft-license Key

1. Type command `host2txt`, copy the Serial Number generated, and then paste into an email to be sent to MakeAFP Support at [support@makeafp.com](mailto:support@makeafp.com) to request a software license key for your system.
2. Once your HOST2TXT Transform License key file `host2txt.lic` is received, copy it into your HOST2TXT installation path, default path is:

```
/usr/share/host2txt
```

---

### Uninstalling HOST2TXT on Linux

To uninstall HOST2TXT Transform on a Linux server:

If installed HOST2TXT on the default installation path `/usr/share/HOST2TXT`, type the following command:

```
sudo sh host2txt_install.bin --uninstall
```

If installed HOST2TXT on a user define specific path, type the following command:

```
sudo sh host2txt_install.bin your_host2txt_path_name --uninstall
```

---

## Chapter 4. HOST2TXT Command

HOST2TXT Transform provides an easy-to-use high-performance command-line program, to enable you quickly transform high-volume IBM mainframe line data to the text data for the open systems.

---

### HOST2TXT Command Syntax

HOST2TXT command is designed to be easy to use, only some of the basic flag parameters are needed to control the HOST2TXT Transform.

#### Command syntax

```
host2txt [hostFile] [txtFile] [options]
```

#### Parameters

*hostFile* `

Optional, specify the fully qualified filename of the input IBM mainframe line data file, wildcard characters(\* and ?) are allowed for the multiple input files, alternatively, you may transform all input files from a specific path specified by the flag parameter *-i inPath*.

*txtFile*

Optional, specify the filename of output text file, if it is not specified then its filename forms by the input file base name with filename extension \*.txt, and output to the current path.

*-i inPath*

Optional, specify the input path from which to process all IBM mainframe line data files, default is the current path if it is specified.

*-ln n*

Optional, specify the output text line delimiter, valid values are:

|   |                                                               |
|---|---------------------------------------------------------------|
| 0 | Default value, on Windows systems: \r\n; On Linux systems: \n |
| 1 | \n for Linux/Unix systems                                     |
| 2 | \r\n for Windows/DOS systems                                  |

*-o outPath*

Optional, specify the output path of the text files, default is the current path if it is specified.

*-O dynamicOutPath*

Optional, specify the convention to construct the dynamic output directories for the splitting of text data.

The following keywords are supported for auto-split text data into the dynamic directories:

|                                                                                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| (yy), (yyyy)                                                                               | by the date value of current year                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| (mm)                                                                                       | by the date value of current month                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| (dd)                                                                                       | by the date value of current day                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| (HH)                                                                                       | by the time value of current hour                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| (MM)                                                                                       | by the time value of current minute                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| (SS)                                                                                       | by the time value of current second                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| (idx <i>n</i> , <i>column</i> , <i>length</i> )                                            | by the part of generic index value string capturing from a generic index. <i>n</i> indicates the order number of index attribute names specified by the command argument flag - <i>s</i> ; <i>column</i> specifies the byte offset from the beginning of the index value string, a value of "1" refers to its first byte; <i>length</i> specifies the number of bytes to be captured.                                                                                                                                                                                                              |
| (idx <i>n</i> , <i>fieldNo</i> , <i>fieldCol</i> , <i>fieldLen</i> ," <i>delimiters</i> ") | by the part of a generic index value string captured from an AFP index. <i>n</i> indicates the order number of index attribute names specified by the command argument flag - <i>s</i> ; <i>fieldNo</i> specifies the order number of the data fields to be used to construct the index value string; <i>fieldCol</i> specifies the byte offset from the beginning of the data field, a value of "1" refers to its first byte; <i>fieldLen</i> specifies the maximum number of bytes to be captured; <i>delimiters</i> specifies the characters to be used to indicate the end of the data fields. |

**Example:**

Assuming today is May 30, 2023, with e:\visa\ (yyyy)\ (mm)\ (dd) dynamic output directory definition, text data will be split into the following directory:

```
e:\visa\2023\05\30\
```

Assuming command-line flag parameter -s INVOICE is specified, INVOICE value string forms by the convention *x-mm-dd-yy-xxxx-accountNo*, and dynamic output directory definition is defined as:

```
f:\visa\ (idx1,1,1)\ (idx1,9,2)\ (idx1,3,2)\ (idx1,6,2)\ (idx1,12,4)
```

Text data with INVOICE index value A-05-16-12-0301-2340561670 will be split into the directory:

```
f:\visa\A\12\05\16\0301\
```

Assuming command-line flag parameter -s INVOICE is specified, INVOICE value string forms by the convention *x-mm-dd-yy-xxxx-accountNo*, and dynamic output directory definition is defined as:

```
f:\visa\ (idx1,1,1)\ (idx1,9,2)\ (idx1,3,2)\ (idx1,6,2)\ (idx1,12,4)
```

Document with INVOICE index value A-05-16-12-0301-2340561670 will be split into the directory:

```
f:\visa\A\12\05\16\0301\
```

Assuming command-line flag parameter -s "Account No" is specified, its index value string forms by the convention *xxxx-yymmdd-accountNo*, *xxxx* field maximum length may be up to 4 bytes, and dynamic output directory definition is defined as:

f:\debitCard\(\idx1,1,1,4,"-")\(\idx1,2,1,6,"-")\

Document with "Account No" index value A12-120516-2340561670 will be split into the directory:

f:\debitCard\A12\120516\

**-cc**

Optional, indicate that the input line data contains the carriage control codes.

**-v**

Optional, specify that the input line data is in IBM variable record length format, it is the default value if other input data format is not specified.

**-d**

Optional, specify that the input line data record is delimited by IBM mainframe host line-feed hex code x'25', PC carriage-return & line-feed hexcode x'0d0a', or Unix line-feed hexcode x'0a'.

**-l *nnnn***

Specify that the input line data is in fixed record length *nnnn* bytes.

**-list**

List the encoding codepage names.

**-f *fromCP***

Specify the codepage ID of input line data encoding.

**-r**

Optional, replace the existing output text file, the default is to add the filename extension with a sequential number to retain the existing text file.

**-rc "*char*"**

Optional, replace invalid characters from the generic index attribute values with a "*char*" character for the splitting of text output files, the default "*char*" value is blank.

**-t *toCP***

Optional, specify the codepage ID of the output text data encoding, the default is UTF-8 if it is not specified.

**-s *indexes***

Optional, split line data pages by the generic indexes exported from IBM CMOD, the output text file base name will be formed by the index values in the order of index values attribute (GROUP\_FIELD\_NAME) names exported from IBM CMOD. The default text filename delimiter is dot (.) to separate filename fields, the custom delimiter can be specified in the syntax *indexName*[*delimiter*], and invalid characters with filename can be replaced in the syntax {*chars*, *newChar*}, for example:

```
"indexName1{'/,_}[_];indexName2{ ,_}[_];indexName3{%,_-}[_]"
```

**-sd**

Optional, scan and read all sub-folders.

**-si**

Optional, read IBM line data stream from the standard-input.

**-so**

Optional, write text data stream to the standard-output.

**-ss "char"**

Optional, set the delimiter used to append the sequence number suffix to the text output filename in the case if the same split text output filename exists, the default delimiter is the underscore character (\_).

---

## HOST2TXT Command Examples

The following example shows how to use the HOST2TXT command to transform a line data file exported from IBM Content Manager OnDemand, which is encoded in EBCDIC encoding codepage 500 with carriage-control code, output text will be encoded in UTF-8 with filename extension \*.txt.

```
host2txt REPORT.0.TWMD10RPTGRP.ATW0DBMD1.out -cc -f 500
```

## Appendix A. EBCDIC Codepage Summary

| Codepage ID | Description                      | Encoding |
